

## **TRANSDERMAL DRUG DELIVERY DEVICES COMPRISING A POLYURETHANE DRUG RESERVOIR**

### **Field of Invention**

5

The present invention relates to the field of transdermal drug delivery. More specifically, the present invention relates to drug reservoir materials for use in transdermal drug delivery devices. The drug reservoirs of the present invention comprise a polyurethane polymer that can be processed at  
10 temperatures below those that cause degradation of temperature sensitive drugs and/or excipients. The present invention is also directed to tailoring the release characteristics of the polyurethane material in order to accommodate a range of suitable drugs to be delivered from the transdermal drug delivery device and/or provide a range of delivery rates for a particular drug.

15

### **Background of the Invention**

The transdermal route of parenteral drug delivery provides many advantages over other administrative routes. Transdermal drug delivery devices  
20 for delivering a wide variety of drugs or other beneficial agents are described in U.S. Patent Nos. 3,598,122; 3,598,123; 3,731,683; 3,797,494; 4,031,894; 4,201,211; 4,286,592; 4,314,557; 4,379,454; 4,435,180; 4,559,222; 4,568,343; 4,588,580; 4,645,502; 4,698,062; 4,704,282; 4,725,272; 4,781,924; 4,788,062; 4,816,258; 4,849,226; 4,904,475; 4,908,027; 4,917,895; 4,938,759; 4,943,435;  
25 5,004,610; 5,071,656; 5,141,750; 5,342,623; 5,411,740; and 5,635,203, all of which are hereby incorporated in their entirety by reference.

Transdermal drug delivery devices typically fall into one of three categories:

1) Form-Fill-Seal systems wherein the drug is contained within a gel reservoir layer which fills a cavity defined between a rate controlling membrane and a backing layer;

2) Multilaminate systems defined as a transdermal system in which the drug and excipient are formulated into a layer distinct from the adhesive layer. As the name implies the system may consist of two or more layers in addition to the backing layer; and

3) Matrix/monolith (also called "drug-in-adhesive") system defined as a transdermal system in which the drug and excipients are formulated directly into an adhesive; the adhesive and backing make up the system.

Form-Fill-Seal systems and their manufacture are described in U.S. Patent No. 4,379,454, for example. These devices are generally more difficult to manufacture and tend to be bulkier than multilaminates and matrix devices. Thus, systems of this type are less attractive for both manufacturing and cosmetic reasons.

Multilaminate systems are typically manufactured by a solvent casting process as described in U.S. Patent No. 4,286,592, for example, wherein the drug, permeation enhancer, and/or polymeric carrier are mixed with an organic solvent and cast onto a substrate such as a backing layer, rate control membrane, or release liner. The film is then heated to drive off the organic solvent. At least two films are cast (i.e. the drug reservoir and adhesive films) and subsequently laminated together to form a final multilaminate device.

Monoliths are manufactured in a manner similar to the multilaminate process (i.e. solvent casting the drug, excipient, and adhesive polymer components), but consist of a single film. In addition to the solvent casting process described above, hot-melt processing has been disclosed as a process for manufacturing transdermal drug delivery devices as disclosed in, for example, U.S. Patent Nos. 5,273,757, 5,536,759, 5,641,506, 5,662,923, 5,662,926, 5,670,164, and 5,688,523, hereby incorporated in their entirety by

reference. However, both solvent casting and hot-melt processing methods have their drawbacks.

Solvent casting of the polymer layers for transdermal drug delivery systems requires dissolving and/or suspending the drug and/or excipients in a solvent, coating the resulting solution onto a web, then oven drying the coated web to evaporate the solvent from the cast film. Residual solvent must be at a very low concentration since the film is intended for skin contact applications. However, as seen in the above cited patents, the use of solvents in the manufacture of the various layers of transdermal systems is disadvantageous for several reasons.

First, solvent casting requires additional expenses for the solvents, drying and extraction equipment, and even further costs associated with the recovery, separation, or incineration of the solvents. Secondly, the removal of solvent requires the application of elevated temperatures to the polymer film, which can strip the lower molecular weight components, including the drug, from the film and also cause degradation of drug and/or excipient. The temperature may be lowered, in which case the time required to evaporate the solvent is substantially increased. Additionally, the flammability of the solvents and the risk of harm organic solvents pose to human organisms raise additional concerns.

Hot-melt processing, while avoiding the need to remove any solvent, still subjects the polymer, drug, and possible excipients to elevated temperatures and further suffers from higher mixing torques. For example, U.S. Patent Nos. 5,536,759 and 5,662,923 cited above disclose processing temperatures for hot-melt adhesives ranging from 60 °C to 180 °C. U.S. Patent No. 5,662,926 listed above discloses transdermal patches incorporating a drug containing polymer film processed at temperatures of 170 - 200 °C. Such elevated temperatures may cause degradation of drug and/or excipients, particularly if they are heat sensitive. Further, such processes also take time, typically in excess of 0.5 hours, to complete mixing.

Various materials, including polyurethanes, have been proposed for use as drug reservoirs in transdermal drug delivery devices. For example, ethylene vinylacetate (EVA) copolymers are disclosed in U.S. Patent No. 4,144,317 as a suitable drug reservoir material for transdermal drug delivery applications.

5 However, EVA has a limited solubility range for drugs, as the composition can vary from only about 5% vinyl acetate (VA) to about 40% VA before permeability is compromised for any drug. Loading the reservoir beyond saturation with drug and/or permeation enhancer, which is typically required for EVA 40, leads to phase separation. Most permeation enhancers are surfactant in nature and tend  
10 to migrate to interfaces. Phase separation and this migration tendency in turn may lead to delamination of the drug reservoir from the backing and/or adhesive layer(s).

In general, polyurethanes are copolymers of a "hard" segment having a high glass transition temperature ( $T_g$ ) and a "soft" segment (low  $T_g$ ). The hard  
15 segment is typically a diisocyanate such as methylene bis(cyclohexyl) diisocyanate (HMDI) that is chain-extended with a diol, such as 1,4 butane diol. For polyether polyurethanes, the soft segments are typically a polyether alcohol such as poly tetramethylene glycol (PTMEG), poly propylene glycol (PPG), and/or polyethylene glycol (PEG). If the soft segment is composed of PEG  
20 chains, the polyurethane will be very hydrophilic; on the other hand, soft segments made of aromatic polyether (PTMEG) will yield hydrophobic polyurethanes.

One problem associated with polyurethanes of the prior art is their high processing temperature, typically 170 - 250 °C. These high temperatures can  
25 cause degradation of temperature sensitive drugs and/or excipients. This precludes melt-mixing of most drugs into the polyurethane polymer to obtain a drug reservoir for a transdermal drug delivery device.

Polyurethanes for use in transdermal drug delivery devices are known in the art. For example, US Patent No. 4,523,005 discloses polyurethane

polymers formed from a diisocyanate, a high molecular weight polyether polyol, and a low molecular weight glycol chain extender (1,4 butane diol). The polyol should have a molecular weight between 500 - 5000, PTMEG is preferred. As seen in the examples, the polyurethane polymer pellets may be extruded at  
5 temperatures of about 170 °C.

U.S. Patent No. 4,638,043 discloses a drug releasing system comprised of a drug dispensing polyurethane member as a matrix for a therapeutically effective amount of a drug dispersed therein. The polyurethane is a polyurethane acrylic copolymer which is the reaction product of a diisocyanate, a  
10 glycol with a molecular weight between the range of about 500 – 5000, and an acrylyl chain terminator having a molecular weight between the range of 40 – 200 cured by actinic radiation. These polyurethanes are further disclosed in U.S. Patent No. 4,483,759.

Re 32,991 discloses a polyurethane being the reaction product of a  
15 diisocyanate, a macroglycol, and a chain terminator (HEMA). The macroglycol comprises a glycol having a molecular weight in excess of 500 Daltons, and is preferably PPG or PEG.

US Patent No. 4,638,043 discloses polyurethanes comprising polycarbonate glycols having a molecular weight between 500 - 2000 as the  
20 preferred macroglycol.

US Patent No. 5,569,683 discloses polyurethane gel compositions that may include glycols such as propylene glycol, PPG, and PEG.

US Patent No. 4,746,509 discloses transdermal drug delivery devices comprising homogeneous membranes of variable hydrophilicity which enable  
25 the kinetics of the release of drug to be controlled. Heat-reversible, non-cross-linked, film-forming polymers are used which are insoluble in water but may be water-miscible and in which it is possible to vary the hydrophilic character. More particularly, polyurethane/polyoxyethylene glycol/polyoxypropylene glycol copolymers are disclosed as suitable for practice of the invention.

US Patent No. 5,118,779 discloses a hydrophilic polyurethane polymer which is polymerizable in the substantial absence of heat wherein the urethane prepolymer comprises a diisocyanate, a bifunctional component having at least one active hydrogen on each terminal group at least a portion of which is  
5 polyethyleneoxide, and a chain extender. The polyethyleneoxide containing material provides hydrophilicity to the polyurethane polymer and has a molecular weight from about 500 - 3000 Daltons. The balance of this component may be another macroglycol such as PPG or PTMEG. The amount of polyethyleneoxide containing material may range from 5 - 85% by weight of the final elastomer,  
10 depending on the desired hydrophilicity.

Despite the advances in the art, there remains a need in the transdermal drug delivery art to provide a polymer film layer into which the drug is dissolved and/or suspended without the use of solvents. Additionally, the need remains for "tunable" membranes and/or drug reservoirs in transdermal drug delivery and  
15 manufacturing processes thereof which overcome the above problems associated with the prior art.

### Description of Terms

20 As used herein, the term "drug" is to be construed in its broadest sense to mean any material which is intended to produce some biological, beneficial, therapeutic, or other intended effect, such as permeation enhancement, for example, on the organism to which it is applied

As used herein, the term "individual" intends a living mammal and  
25 includes, without limitation, humans and other primates, livestock and sports animals such as cattle, pigs and horses, and pets such as cats and dogs.

As used herein, the term "monoglyceride" refers to a monoglyceride or mixture of monoglycerides of  $C_8$ -<sub>20</sub> fatty acids and includes, without limitation,

glycerol monolaurate (GML), glycerol monooleate (GMO), glycerol monocaprate (GMC), glycerol monocaprylate (GMCL), and glycerol monolinoleate (GMLO).

As used herein, the term "permeation enhancement" intends an increase in the permeability of skin in the presence of a permeation enhancer as compared to permeability of skin in the absence of a permeation enhancer.

As used herein, the term "permeation enhancer" intends an agent or a mixture of agents which acts to increase the permeability of the skin to a drug.

As used herein, the term "permeation-enhancing amount" intends an amount of a permeation enhancer which provides permeation enhancement throughout a substantial portion of the administration period.

As used herein, the phrase "predetermined area of skin" intends a defined area of intact unbroken skin or mucosal tissue. That area will usually be in the range of about 5 cm<sup>2</sup> to about 100 cm<sup>2</sup>.

As used herein, the phrase "sustained time period" or "administration period" intends at least about 8 hours and will typically intend a period in the range of about one to about seven days, preferably about 1 – 3 days.

As used herein, the term "transdermal" intends both percutaneous and transmucosal administration, i.e., passage of drug through a body surface or membrane such as intact unbroken skin or mucosal tissue into the systemic circulation.

### Summary of the Invention

According to this invention, polyurethanes are provided which offer greater versatility for transdermal drug delivery applications. The polyurethanes of this invention can be made to be essentially amorphous and the compositions can be varied over a broad compositional range. By manipulating the ratio of the "hard " and "soft" segments of the polyurethane, a range of permeabilities for a given drug may be obtained. Additionally, by changing the nature of the soft segments, materials of different hydrophobic / hydrophilic nature or drug

solubilities can be obtained. The polyurethanes of this invention can be processed at temperatures lower than about 150 °C, preferably lower than about 100 °C, and most preferably within about 40 – 90 °C without the use of organic solvents.

5       Accordingly, it is one aspect of this invention to provide improved materials for use in transdermal drug delivery systems.

It is another aspect of this invention to provide polyurethanes for transdermal drug delivery applications which offer a range of permeabilities for a drug to be transdermally administered.

10       It is yet another aspect of this invention to provide a more easily processed polyurethane for transdermal drug delivery applications.

It is yet another aspect of this invention to provide drug reservoirs and membranes for transdermal drug delivery devices which can be processed at process temperatures of less than about 150 °C, preferably less than about 100 °C, most preferably within about 40 - 90 °C without the use of organic solvents.

15       It is yet another aspect of this invention to provide a matrix material for transdermal drug delivery applications which is substantially free of residual solvent.

20       These and other aspects of this invention will be made clear from the description that follows, which is understood to include equivalents thereof and is not to be limited by the specific disclosure and examples.

### **Brief Description of the Drawings**

Figure 2 is a cross-section view through another embodiment of this invention prior to application to the skin.

Figure 3 is a cross-section view through another embodiment of this invention prior to application to the skin.

Figure 4 depicts the release rate of fentanyl from devices comprising polyurethane reservoirs according to this invention.

5

### Detailed Description

The present invention is directed to polyurethanes particularly suited for transdermal drug delivery devices and applications. The polyurethanes of this invention provide a greater degree of versatility as variations in processibility, stability, and drug permeability are all enhanced. The polyurethanes of the present invention may be processed into films for incorporation into transdermal drug delivery devices at temperatures less than about 150 °C without the use of organic solvents so that drug(s) and/or excipients can be directly incorporated into the polyurethane polymer by melt-mixing. The polyurethanes can be used as drug reservoirs as well as rate controlling membranes for transdermal drug delivery devices. Permeation of both hydrophilic and hydrophobic drugs can be controlled using the polyurethanes of this invention.

Referring to Figure 1, a preferred embodiment of a transdermal therapeutic system according to this invention comprises transdermal delivery device 10 comprising a polyurethane drug reservoir 12 containing at least one drug and/or a permeation enhancer dispersed and/or dissolved therein. Reservoir 12 is sandwiched between a backing 14 and an in-line contact adhesive layer 16. The device 10 adheres to the surface of the skin 18 by means of the adhesive layer 16. The adhesive layer 16 may optionally contain the permeation enhancer and/or drug. A removable release liner (not shown in FIG. 1) is normally provided along the exposed surface of adhesive layer 16 and is removed prior to application of device 10 to the skin 18. Optionally, a rate-controlling membrane (not shown) may be present between the reservoir 12 and

25

the adhesive layer 16. Additionally, a non-rate controlling tie layer membrane as disclosed in US Patent No. 5,635,203, incorporated herein in its entirety by reference, may be present between the reservoir 12 and adhesive 16 in any of the embodiments depicted in Figures 1- 3.

5        Although the preferred embodiments of this invention utilize an in-line adhesive as is shown in Figure 1, other means for maintaining the system on the skin can be employed. Such means include a peripheral ring of adhesive outside the path of the drug from the system to the skin or the use of other fastening means such as buckles, belts, and elastic arm bands.

10        Alternatively, as shown in FIG. 2, transdermal therapeutic device 20 may be attached to the skin or mucosa of a patient by means of an adhesive overlay 22. Device 20 is comprised of polyurethane drug reservoir 12 containing at least one drug and/or a permeation enhancer dispersed and/or dissolved therein. A backing layer 14 is provided adjacent to one surface of reservoir 12. Adhesive  
15        overlay 22 maintains the device on the skin and may be fabricated together with, or provided separately from, the remaining elements of the device. With certain formulations, the adhesive overlay 22 may be preferable to the in-line contact adhesive 16 as shown in FIG. 1. Backing layer 14 is preferably slightly larger than reservoir 12, and in this manner prevents the materials in reservoir 12 from  
20        adversely interacting with the adhesive in overlay 22. Optionally, a rate-controlling membrane (not shown in FIG. 2) may be provided on the skin-proximal side of reservoir 12. A removable release liner 24 is also provided with device 20 and is removed just prior to application of device 20 to the skin.

25        In FIG. 3, transdermal delivery device 30 comprises a polyurethane drug and permeation enhancer reservoir ("drug reservoir") 12 substantially as described with respect to FIG. 1. Permeation enhancer reservoir ("enhancer reservoir") 26 comprises the permeation enhancer dispersed throughout and contains drug at or below saturation, when in equilibrium with the drug reservoir 12. Enhancer reservoir 26 is preferably made from substantially the same

matrix as is used to form drug reservoir 12. A rate-controlling membrane 28 for controlling the release rate of the permeation enhancer from enhancer reservoir 26 to drug reservoir 12 is placed between the two reservoirs. A rate-controlling membrane (not shown in FIG. 3) for controlling the release rate of the enhancer and/or drug from drug reservoir 12 to the skin may also optionally be utilized and would be present between adhesive layer 16 and reservoir 12.

Superimposed over the permeation enhancer reservoir 26 of device 30 is a backing 14. On the skin-proximal side of reservoir 12 are an adhesive layer 16 and a removable liner 24 which would be removed prior to application of the device 30 to the skin.

It is preferable for the devices depicted in Figures 1 – 3 to control the rate at which the drug is released from the device to the skin or mucosa of a host. In accordance with one aspect of this invention, the in-line contact adhesive 16 is capable of controlling the rate at which the drug is released to the skin or mucosa surface. Alternatively, a rate controlling membrane is utilized for this purpose as set forth above. The rate-controlling membrane may be fabricated from permeable, semipermeable or microporous materials which are known in the art to control the rate of agents into and out of delivery devices and having a permeability to the permeation enhancer lower than that of drug reservoir 12.

Suitable materials include, but are not limited to, polyethylene, polyvinyl acetate, ethylene n-butyl acetate and ethylene vinyl acetate copolymers. According to another embodiment, the polyurethane drug reservoir layer controls the rate at which drug is released from the system as discussed in greater detail below. Polyurethanes of this invention can also be used as rate controlling membranes distinct from the drug reservoir.

Permeation enhancers suitable for practice of this invention may be any permeation enhancer known in the art to increase permeability of drugs through skin and includes, but is not limited to, those disclosed in the above cited patents. Preferably, the permeation enhancer comprises a permeation

enhancing amount of a permeation enhancer including, but not limited to monoglycerides, C<sub>10</sub> - C<sub>20</sub> fatty acid esters including ethyl palmitate and isopropyl myristate; acyl lactylates such as caproyl lactic acid and lauroyl lactic acid; dimethyl lauramide; dodecyl (lauryl) acetate; lactate esters such as lauryl  
5 lactate, and myristyl lactate; monoalkyl ethers of polyethyleneglycol and their alkyl or aryl carboxylic acid esters and carboxymethyl ethers such as polyethylene glycol-4 lauryl ether (Laureth-4) and polyethylene glycol-2 lauryl ether (Laureth-2); Myreth-3, myristyl sarcosine, and methyl laurate.

The backing material is selected from materials known in the art and is  
10 preferably an occlusive film. Preferred materials include multilaminate films including, but not limited to medium density polyethylene (MDPE) / polyester / aluminum / ethylene vinylacetate (EVA) laminates, polyolefin/polyurethane films such as low density polyethylene/polyurethane laminates, or medium density polyethylene / polyurethane laminates.

15 Adhesives suitable for use with the present invention are known in the art as disclosed, for example, in the above cited patents and are preferably pressure sensitive adhesives. Such pressure sensitive adhesives include, but are not limited to, polysiloxanes, polyacrylates, polyurethanes, acrylic adhesives including cross linked or uncross linked acrylic copolymers, vinyl acetate  
20 adhesives, ethylene vinylacetate copolymers, and natural or synthetic rubbers including polybutadienes, polyisoprenes, and polyisobutylene adhesives; and mixtures and graft copolymers thereof

It is believed that this invention has utility in connection with the delivery of drugs within the broad class normally delivered through body surfaces and  
25 membranes, including skin. In general, this includes therapeutic agents in all of the major areas, including, but not limited to, ACE inhibitors, adenylyltransferase hormones, adrenergic neuron blocking agents, adrenocortical steroids, inhibitors of the biosynthesis of adrenocortical steroids, alpha-adrenergic agonists, alpha-adrenergic antagonists, selective alpha-two-adrenergic agonists, analgesics,

antipyretics and anti-inflammatory agents, androgens, local and general anesthetics, antiaddictive agents, antiandrogens, antiarrhythmic agents, antiasthmatic agents, anticholinergic agents, anticholinesterase agents, anticoagulants, antidiabetic agents, antidiarrheal agents, antidiuretic, antiemetic  
5 and prokinetic agents, antiepileptic agents, antiestrogens, antifungal agents, antihypertensive agents, antimicrobial agents, antimigraine agents, antimuscarinic agents, antineoplastic agents, antiparasitic agents, antiparkinson's agents, antiplatelet agents, antiprogestins, antithyroid agents, antitussives, antiviral agents, atypical antidepressants, azaspirodecanediones,  
10 barbituates, benzodiazepines, benzothiadiazides, beta-adrenergic agonists, beta-adrenergic antagonists, selective beta-one-adrenergic antagonists, selective beta-two-adrenergic agonists, bile salts, agents affecting volume and composition of body fluids, butyrophenones, agents affecting calcification, calcium channel blockers, cardiovascular drugs, catecholamines and  
15 sympathomimetic drugs, cholinergic agonists, cholinesterase reactivators, dermatological agents, diphenylbutylpiperidines, diuretics, ergot alkaloids, estrogens, ganglionic blocking agents, ganglionic stimulating agents, hydantoins, agents for control of gastric acidity and treatment of peptic ulcers, hematopoietic agents, histamines, histamine antagonists, 5-hydroxytryptamine  
20 antagonists, drugs for the treatment of hyperlipoproteinemia, hypnotics and sedatives, immunosuppressive agents, laxatives, methylxanthines, monoamine oxidase inhibitors, neuromuscular blocking agents, organic nitrates, opioid analgesics and antagonists, pancreatic enzymes, phenothiazines, progestins, prostaglandins, agents for the treatment of psychiatric disorders, retinoids,  
25 sodium channel blockers, agents for spasticity and acute muscle spasms, succinimides, thioxanthines, thrombolytic agents, thyroid agents, tricyclic antidepressants, inhibitors of tubular transport of organic compounds, drugs affecting uterine motility, vasodilators, vitamins and the like, alone or in combination.

For use as a drug reservoir in a transdermal drug delivery device according to this invention, the polyurethane preferably satisfies the following criteria:

1) Sufficient flexibility such that the matrix material exhibits a modulus  
5 within the range of about 0.1MPa - 100 MPa at room temperature, preferably 0.5 – 10 Mpa;

2) Sufficient drug and/or permeation enhancer loading at a matrix thickness of about 1-12 mils, preferably 2 - 6 mils such that a therapeutically effective amount of drug is delivered from the device to an individual throughout  
10 the administration period without delamination of any of the device layers; and

3) Process temperature of less than about 150 °C, preferably less than about 100 °C, and most preferably about 40 – 90 °C without the use of organic solvents.

The polyurethanes suitable for practice of this invention are the reaction  
15 product of aliphatic organic diisocyanates, high molecular weight polyether polyols, and low molecular weight glycols and may be prepared according to methods known in the art as disclosed in, for example, U.S. Patent No. 4,523,005. Polyurethanes suitable for practice of this invention include those provided by Thermedics, Inc. of Woburn, MA under the tradename Tecoflex®  
20 SG 80A, EG 80A, EG 85A, 24B, 38C, 57B, 163C, 166A, LM 50D, and LM 70A. Tecoflex LM 70A is the preferred polyurethane for use in the transdermal drug delivery systems according to this invention.

Solubilities of the permeation enhance GML and laurydone in representative Tecoflex® polyurethanes are given below. Solubility in EVA is  
25 included for comparison

Table 1

Tecoflex® Polyurethane	Solubility of GML	Solubility of laurydone
24B	5-7 wt%	<15 wt%
38C	6-8 wt%	<13 wt%
163C	<4 wt%	20-22 wt%
166A	4-5 wt%	15-20 wt%
57B	6-8 wt%	13-16 wt%
LM-70A	5-6 wt%	> 12 wt%
Control		
EVA	2-3wt%	10-14 wt%

By manipulating the ratio of the hard and soft components of the polyurethane, a range of permeabilities for a given drug can be obtained for the polyurethane materials. Thus, the polyurethane material can be tailored to control the rate of release of drug from the device. For example, the ratio of the diisocyanate to the polyol can be varied by changing the amount of polyol in order to yield materials with different processibilities and diffusivities. In this manner, drug delivery devices which provide different delivery rates for the same or different drugs can be produced. If the ratio is high, the diffusivity is low and vice versa. The process temperature can be lowered by incorporating a second chain extender into the polyurethane formulation that disrupts the crystallinity formed by the hard segment (i.e. HDMI). Such chain extenders should also be compatible with the drug and any excipients such as permeation enhancers, for example, so that sufficient loadings of drug and / or excipients in the drug reservoir layer may be achieved.

In another aspect, by changing the nature of the soft segment, polyurethanes having different hydrophobic / hydrophilic character or drug solubility can be obtained in order to accommodate different drugs. According to this embodiment, a preferred soft segment monomer is propylene glycol.

Polyurethanes of intermediate hydrophilicity are obtained by either blending or copolymerizing two types of soft segment monomers.

According to a preferred embodiment, the polyurethane has a process temperature of less than about 150 °C, preferably less than about 100 °C, most preferably between about 40 - 90 °C and a modulus value of between about 0.1 – 100 MPa (at room temperature). Preferred polyurethanes comprise polyether alcohols as the soft segment and a diisocyanate as the hard segment, and a diol as a chain extender. Preferred polyether alcohols include PTMEG having a molecular weight within the range of about 1000 – 2000 Daltons, and PPG. PPG is the particularly preferred soft segment as it provides polyurethanes that are more stable under elevated temperatures of greater than approximately 150 °C. 1,4 butane diol is a preferred chain extender, and HMDI is the preferred hard segment.

When used as the drug reservoir for a transdermal drug delivery device, the polyurethane polymer comprises about 50 – 98 wt%, preferably 75 – 95 wt% of the total weight of the drug reservoir. According to this embodiment, the polyurethane drug reservoir contains 0.1 – 40 wt%, preferably 1 – 20 wt %, of a drug to be delivered and 0 – 40 wt%, preferably 2 – 20 wt% of a permeation enhancer.

A preferred embodiment of this invention is directed to transdermal drug delivery devices for administering fentanyl. Devices for the transdermal administration of fentanyl are known in the art as disclosed in, for example, U.S. Patent Nos. 4,470,962; 4,588,580; 4,626,539; 4,906,463; 4,911,916; 5,006,342; 5,186,939; 5,474,783; 5,762,952; and JP 142210, which are hereby incorporated in their entirety by reference. According to this embodiment, a transdermal drug delivery device for administering fentanyl comprises:

- a) a backing layer;
- b) a drug reservoir comprising about 75 – 95 wt% of a polyether polyurethane having a process temperature of less than 150 °C, preferably less

than 100 °C, most preferably about 40 – 90 °C, wherein the polyurethane drug reservoir layer contains:

i) 1 – 10 wt%, preferably 3 – 8 wt%, most preferably 5 – 7 wt% fentanyl base;

5 ii) 0 – 20 wt% of a permeation enhancer, preferably 2 – 17 wt% permeation enhancer, and most preferably 4 – 15 wt% of a permeation enhancer; and

c) means for maintaining the device in fentanyl transmitting relationship with a body surface or membrane.

10 The preferred polyurethane according to this embodiment is Tecoflex® LM 70A available from Thermedics of Woburn MA. According to this embodiment, it is preferable to provide the drug reservoir with fentanyl at or below saturation, most preferably below saturation in order to avoid phase separation. It is also preferable to provide permeation enhancer at or below  
15 saturation in the drug reservoir.

Devices according to this embodiment are preferably multilaminate devices comprising an in-line pressure sensitive adhesive as the means for maintaining the device in fentanyl transmitting relationship with a body surface or membrane. Preferably, the solubility of the adhesive for fentanyl and any  
20 permeation enhancer is less than the solubility of the drug reservoir for fentanyl and any permeation enhancer. Preferably, the adhesive contains less than about 5 wt% fentanyl after equilibration. Acrylate pressure sensitive adhesives are preferred. Examples of acrylate adhesives include NS87-2100, NS87-2287 and NS87-2516 provided by National Starch and Chemical Co. NS87-2287 is a  
25 solution polyacrylate comprising vinyl acetate, 2-ethylhexyl acrylate, hydroxyethyl acrylate, and glycidyl methacrylate monomers and is the preferred adhesive according to this embodiment. It contains no crosslinking agent and is available as a 50% solids solution in ethyl acetate.

According to this embodiment, the backing layer is preferably medium density polyethylene (MDPE) / polyester / aluminum / ethylene vinylacetate (EVA) laminates or a low density polyethylene / polyurethane laminate.

Polyolefin / polyurethane films adhere well to the polyurethane drug reservoirs of this invention, while medium density polyethylene (MDPE) / polyester / aluminum / ethylene vinylacetate (EVA) laminates have been observed to yield slightly higher flux with slightly less adhesion to the polyurethane reservoir.

Preferred permeation enhancers according to this embodiment for administering fentanyl include monoglycerides and lauryl pyroglutamate. Lauryl pyroglutamate may be obtained from DD Chemco (Northridge, CA) under the tradename Laurydone® (U.C.I.B., Anet, France).

Having thus generally described our invention, the following specific examples describe preferred embodiments thereof but are not intended to limit the invention in any manner.

### Example 1

Drug reservoirs were prepared by mixing fentanyl base, permeation enhancer, and polyurethane granules in a Brabender mixer (30 cc) provided with a heater in order to melt-mix the formulations. After mixing for approximately 30 minutes, the drug reservoir formulation was calendered into a 5 mil thick film. The film was then laminated to a backing layer (Medpar®, 3M, St. Paul, MN) which was subsequently laminated to an acrylate adhesive layer (NS87-2287, National Starch and Chemical Co., Bridgewater, NJ). Circular systems having a 2.54 cm<sup>2</sup> surface area were punched. The mix had a process temperature of approximately 65 °C. System compositions are shown in Table 2. A Duragesic® (Janssen Pharmaceuticals) system prepared according to the method set forth in Example 1 of U.S. Patent No. 4,588,580 was used as the

control and had its surface area outside 2.54 cm<sup>2</sup> masked to normalize surface area available for drug delivery.

**Table 2****Drug/Permeation Enhancer Reservoir Composition**

Sample	Formulation	Weight %
1	Fentanyl/ laurydone/ polyurethane	6/15/79
2	Fentanyl/ laurydone/ polyurethane	6/10/84
3	Fentanyl/ laurydone/GML/polyurethane	6/7.5/2.5/84
9	control	

Circular pieces of human epidermis were placed with stratum corneum facing up. The release liner of the laminate was removed and the fentanyl releasing side of the system was centered over the stratum corneum side of the epidermis which had been blotted dry just prior to use. The edges of epidermis were then folded around the system so that none of the system edge was exposed to the receptor solution. This assembly was then mounted on a Teflon® holder of a release rate rod using nylon mesh and metal string. A known volume of receptor solution (0.05M KH<sub>2</sub>PO<sub>4</sub> / K<sub>2</sub>HPO<sub>4</sub>, pH 6.5) was then placed in a test tube and was equilibrated at 35°C. The test tube was placed in a water bath and maintained at 35°C. The Teflon rod with system and epidermis attached was then reciprocated within the test tube by attaching the rod to a motor which caused constant vertical mixing.

At given time intervals, the entire receptor solution was removed from the test tubes and replaced with an equal volume of fresh receptor solutions previously equilibrated at 35°C. The receptor solutions are stored in capped vials at 4 °C until assayed for fentanyl content by HPLC. From the drug concentration and the volume of the receptor solutions, the area of permeation and the time interval, the flux of the drug through the epidermis was calculated

as follows: (drug concentration X volume of receptor)/(area x time) = flux ( $\mu\text{g}/\text{cm}^2 \cdot \text{hr}$ ). The *in vitro* flux of fentanyl through epidermis at 35 °C is shown in Figure 4.
